

## WORKSHOP DETAILS

- Build a Full-Stack application that has 3 input fields “longitude, latitude, radius” and displays nearby places result on a web page. (If you can, display the result on Google Map.)
  - You can use any technology for web side. (VueJS, ReactJS or Angular 7+ is a big plus.)
  - Application MUST have a backend server that accepts GET requests as REST API on port 8070 (You should use Java8+.)
  - Get API should accept longitude, latitude, radius values as a query parameter to make a nearby search request via Google Places API and return the result as response.
  - Responses from Google Places API should be saved and if same request comes again the response should be returned from DB.
- 
- Workshop application is supposed to be deployed on web. (Platform is up to you.)
  - Your GitHub Repository for source codes is expected to be shared. (Work-process will be reviewed through your commits. Repositories consisting of single commit will be leaved out of assessment!)

**!!Good Luck!!**
